Lecture VII - NumPy and Pandas for Scientific Computing Programming with Python

Dr. Tobias Vlćek

Quick Recap of the last Lecture

NumPy Module

What is NumPy?

- · NumPy is a package for scientific computing in Python
- · Provides support for large, multi-dimensional arrays and matrices
- · Wide range of mathematical functions to operate on these arrays
- · Python lists can be slow Numpy arrays are much faster

. . .

i Note

The name of the package comes from Numerical Python.

Why is NumPy so fast?

- NumPy arrays are stored in a contiguous block of memory
- This allows for efficient memory access patterns
- Operations are implemented in the languages C and C++

How to get started

- 1. Install NumPy using pip install numpy
- 2. In Thonny, use Tools -> Manage Packages... to install NumPy
- 3. Import NumPy in a script using import numpy as np
- 4. You are ready to go!

. . .

```
import numpy as np
x = np.array([1, 2, 3, 4, 5])
type(x)
```

numpy.ndarray

. . .

i Note

You don't have to use as np. But it is a common practice to do so.

Creating Arrays

- The backbone of Numpy is the so called ndarray
- · Can be initialized from different data structures:

```
import numpy as np
array_from_list = np.array([1, 1, 1, 1])
print(array_from_list)

[1 1 1 1]
import numpy as np
array_from_tuple = np.array((2, 2, 2, 2))
print(array_from_tuple)

[2 2 2 2]
```

Hetergenous Data Types

• It is possible to store different data types in a ndarray

```
import numpy as np
array_different_types = np.array(["s", 2, 2.0, "i"])
print(array_different_types)

['s' '2' '2.0' 'i']
...

i Note
```

Not recommended, as it can lead to performance issues. I possible, keep them homogenous.

Creating Prefilled Arrays

Often used to improve performance by allocating memory upfront

```
np.zeros(shape): to create an array of zeros
np.ones(shape): to create an array of ones
np.random.rand(shape): to create an array of random values
np.arange(start, stop, step): evenly spaced values
np.linspace(start, stop, num): evenly spaced values
```

i Note

11010

The shape refers to the size of the array. It can have one or multiple dimensions.

Dimensions

- The shape is specified as tuple in these arrays
- (2) or 2 creates a 1-dimensional array (vetor)

- (2,2) creates a 2-dimensional array (matrix)
- (2,2,2) creates a 3-dimensional array (3rd order tensor)
- (2,2,2,2) creates a 4-dimensional array (4th order tensor)

• ...

Arrays in Action

Task: Complete the following task

```
# Create a 3-dimensional tensor with filled with ones
# You can choose the shape of the tensor, but it should have 200 elements
# Sum over all values of the tensor
# Print the shape of the tensor using the method shape()
# Print the dtype of the tensor using the method dtype()
# Print the size of the tensor using the method size()
```

Indexing and Slicing

- · Accessing and slicing ndarray elements works as before
- In higher dimensions we can access elements using multiple indices

. . .

Question: What do you expect will be printed?

```
import numpy as np
x = np.random.randint(0, 10, size=(3, 3))
print(x)
print("---")
print(x[0:2,0:2])

[[7 5 9]
  [1 2 4]
  [9 2 1]]
---
[[7 5]
  [1 2]]
```

Data Types

- Numpy provides data types as characters
- i: integer
- ъ: boolean
- f: float
- S: string
- U: unicode
- The type can be checked by calling the .dtype attribute

```
string_array = np.array(["Hello", "World"])
string_array.dtype
```

```
dtype('<U5')
```

Enforcing Data Types

· We can also provide the type when creating arrays

. . .

```
x = np.array([1, 2, 3, 4, 5], dtype = 'f')
print(x.dtype)
```

float32

. . .

· Or we can change them for existing arrays

```
x = np.array([1, 2, 3, 4, 5], dtype = 'f')
print(x.astype('i').dtype)
```

int32

. . .

Note

Note, how the types are specified as int32 and float32.

Joining Arrays

- You can use concatenate two join arrays
- With axis you can specify the dimension
- Even easier in 2-dimensions is hstack() and vstack()

. .

Question: What do you expect will be printed?

```
import numpy as np
ones = np.array((1,1,1,1))
twos = np.array((1,1,1,1)) *2
print(np.vstack((ones,twos)))
print(np.hstack((ones,twos)))
[[1 1 1 1]
```

Common Methods

[2 2 2 2]] [1 1 1 1 2 2 2 2]

- sort(): sort the array from low to high
- reshape(): reshape the array into a new shape
- flatten(): flatten the array into a 1D array
- squeeze(): squeeze the array to remove 1D entries
- transpose(): transpose the array

? Tip

Try experiment with these methods, as they can make your work later much easier.

Iterating over Arrays

- Naturally, we can also loop over a ndarray
- •

Ufuncs

• To increase the speed even further, we can use

Filter

•

Pandas Module

What is Pandas?

- Pandas is a data manipulation and analysis library
- · It provides data structures like DataFrames and Series
- · It also provides tools for data cleaning, analysis, and visualization

How to install Pandas

Creating DataFrames

- Use the pd.DataFrame (data, index, columns) function to create a DataFrame from a dictionary
- Use the pd.DataFrame(data, index, columns) function to create a DataFrame from a dictionary
- Use the pd.DataFrame(data, index, columns) function to create a DataFrame from a dictionary

Basic Operations

- Use the df.head() method to display the first few rows of a DataFrame
- Use the df.tail() method to display the last few rows of a DataFrame
- Use the df.info() method to display information about a DataFrame
- Use the df.describe() method to display summary statistics about a DataFrame
- Use the df.columns attribute to access the column names of a DataFrame
- Use the df.index attribute to access the index of a DataFrame
- Use the df.values attribute to access the values of a DataFrame

Subsetting DataFrames

- Use the df.loc[row_indexer, column_indexer] method to access a specific element of a DataFrame
- Use the df.iloc[row_indexer, column_indexer] method to access a specific element of a DataFrame

Filtering DataFrames

- Use the df [df ['column'] > value] method to filter a DataFrame
- Use the df [df ['column'].isin(values)] method to filter a DataFrame

Grouping DataFrames

- Use the df.groupby('column').sum() method to group a DataFrame and calculate the sum of a column
- Use the df.groupby('column').mean() method to group a DataFrame and calculate the mean of a column
- Use the df.groupby('column').count() method to group a DataFrame and count the number of elements in a column
- Use the df.groupby('column').size() method to group a DataFrame and count the number of elements in a column

Excel Files

- Excel files can be read using the pd.read_excel(file_path) function
- Excel files can be written using the df.to_excel(file_path) method
