# Lecture VII - NumPy for Scientific Computing

### Programming with Python

Dr. Tobias Vlćek Kühne Logistics University Hamburg - Fall 2025

## Quick Recap of the last Lecture

### Modules

- Modules are .py files containing Python code
- They are used to organize and reuse code
- They can define functions, classes, and variables
- Can be imported into other scripts

. . .

Ţip

We can import entire modules or individual functions, classes or variables.

#### Standard Libraries

- Python includes many built-in modules like:
  - random provides functions for random numbers
  - os allows interaction with the operating system
  - csv is used for reading and writing CSV files
  - ▶ re is used for working with regular expressions

### Packages

- Packages are collections of modules
- Often available from the Python Package Index (PyPI)
- Install using uv add <package\_name>
- Virtual environments help manage dependencies

. . .

♀ Tip

Virtual environments are not that important for you right now, as they are mostly used if you work on several projects with different dependecies at once.

## NumPy Module

### What is NumPy?

- NumPy is a package for scientific computing in Python
- Provides large, multi-dimensional arrays and matrices
- Wide range of functions to operate on these
- Python lists can be slow Numpy arrays are much faster

. . .

#### i Note

The name of the package comes from Numerical Python.

### Why is NumPy so fast?

- Arrays are stored in a contiguous block of memory
- This allows for efficient memory access patterns
- Operations are implemented in the languages C and C++

. . .

Question: Have you heard of C and C++?

### How to get started

- 1. Install NumPy using uv add numpy
- 2. Import NumPy in a script using import numpy as np

. . .

```
import numpy as np
x = np.array([1, 2, 3, 4, 5]); type(x)
```

numpy.ndarray

. . .

#### **i** Note

You don't have to use as np. But it is a common practice to do so.

### **Creating Arrays**

- The backbone of Numpy is the so called ndarray
- Can be initialized from different data structures:

```
import numpy as np
```

```
array_from_list = np.array([1, 1, 1, 1])
print(array_from_list)
```

```
[1 1 1 1]
```

```
import numpy as np
array_from_tuple = np.array((2, 2, 2, 2))
print(array_from_tuple)
```

```
[2 2 2 2]
```

### Hetergenous Data Types

• It is possible to store different data types in a ndarray

```
import numpy as np
array_different_types = np.array(["s", 2, 2.0, "i"])
print(array_different_types)
```

```
['s' '2' '2.0' 'i']
```

. . .

#### **i** Note

But it is mostly not recommended, as it can lead to performance issues. If possible, try to keep the types homogenous.

### **Prefilled Arrays**

Improve performance by allocating memory upfront

- np.zeros(shape): to create an array of zeros
- np.random.rand(shape): array of random values
- np.arange(start, stop, step): evenly spaced
- np.linspace(start, stop, num): evenly spaced

. .

#### i Note

The shape refers to the size of the array. It can have one or multiple dimensions.

#### **Dimensions**

- The shape is specified as tuple in these arrays
- (2) or 2 creates a 1-dimensional array (vetor)
- (2,2) creates a 2-dimensional array (matrix)
- (2,2,2) 3-dimensional array (3rd order tensor)
- (2,2,2,2) 4-dimensional array (4th order tensor)
- ...

### Computations

- We can apply operations to the entire array at once
- This is much faster than applying them element-wise

. . .

```
import numpy as np
x = np.array([1, 2, 3, 4, 5])
x + 1
```

```
array([2, 3, 4, 5, 6])
```

### Arrays in Action

Task: Practice working with Numpy:

```
# TODO: Create a 3-dimensional tensor with filled with zeros
# Choose the shape of the tensor, but it should have 200 elements
# Add the number 5 to all values of the tensor

# Your code here
assert sum(tensor) == 1000

# TODO: Print the shape of the tensor using the method shape()
# TODO: Print the dtype of the tensor using the method dtype()
# TODO: Print the size of the tensor using the method size()
```

### **Indexing and Slicing**

- Accessing and slicing ndarray works as before
- Higher dimension element access with multiple indices

. . .

Question: What do you expect will be printed?

```
import numpy as np
x = np.random.randint(0, 10, size=(3, 3))
print(x); print("---")
print(x[0:2,0:2])
```

```
[[3 9 8]
  [1 7 2]
  [5 0 8]]
---
  [[3 9]
  [1 7]]
```

### Data Types

- Numpy provides data types as characters
- i: integer
- b: boolean
- f: float
- S: string
- U: unicode

. . .

```
string_array = np.array(["Hello", "World"]); string_array.dtype
```

```
dtype('<U5')
```

### **Enforcing Data Types**

• We can also provide the type when creating arrays

. . .

```
x = np.array([1, 2, 3, 4, 5], dtype = 'f'); print(x.dtype)
```

```
float32
```

. . .

• Or we can change them for existing arrays

```
x = np.array([1, 2, 3, 4, 5], dtype = 'f'); print(x.astype('i').dtype)
```

int32

. . .

### **i** Note

Note, how the types are specified as int32 and float32.

Sidenote: Bits

Question: Do you have an idea what 32 stands for?

. . .

- It's the number of bits used to represent a number
  - ▶ int16 is a 16-bit integer
  - float32 is a 32-bit floating point number
  - ▶ int64 is a 64-bit integer
  - ► float128 is a 128-bit floating point number

### Why do Bits Matter?

- They matter, because they can affect:
  - the performance of your code
  - the precision of your results

. . .

- That's why numbers can have a limited precision!
  - An int8 has to be in the range of −128 to 127
  - ► An int16 has to be in the range of -32768 to 32767

. . .

Question: Size difference between int16 and int64?

### Joining Arrays

- You can use concatenate two join arrays
- With axis you can specify the dimension
- In 2-dimensions <a href="https://

. .

Question: What do you expect will be printed?

```
import numpy as np
ones = np.array((1,1,1,1))
twos = np.array((1,1,1,1)) *2
print(np.vstack((ones,twos))); print(np.hstack((ones,twos)))
```

```
[[1 1 1 1]
[2 2 2 2]]
[1 1 1 1 2 2 2 2]
```

#### Common Methods

- sort(): sort the array from low to high
- reshape(): reshape the array into a new shape
- flatten(): flatten the array into a 1D array
- squeeze(): squeeze the array to remove 1D entries
- transpose(): transpose the array

. . .

Ţip

Try experiment with these methods, they can make your work much easier.

### Speed Differences in Action

Task: Complete the following task to practice with Numpy:

```
# TODO: Create a 2-dimensional matrix with filled with ones of size 1000 x
1000.
# Afterward, flatten the matrix to a vector and loop over the vector.
# In each loop iteration, add a random number between 1 and 10000.
# TODO: Now, do the same with a list of the same size and fill it with
random numbers.
# Then, sort the list as you have done with the Numpy vector before.
# You can use the 'time' module to compare the runtime of both approaches.
import time
start = time.time()
# Your code here
end = time.time()
print(end - start) # time in seconds
```

## That's it for today!

#### i Note

And that's it for todays lecture!

You now have the basic knowledge to start working with scientific computing.

#### Literature

### **Interesting Books**

- Downey, A. B. (2024). Think Python: How to think like a computer scientist (Third edition). O'Reilly. <u>Link to free online version</u>
- Elter, S. (2021). Schrödinger programmiert Python: Das etwas andere Fachbuch (1. Auflage). Rheinwerk Verlag.

. . .

For more interesting literature to learn more about Python, take a look at the <u>literature</u> <u>list</u> of this course.
